

Food Delivery Business Analytics — Power BI Dashboard Guide & Insights

Dashboard Overview :

This Power BI dashboard provides an interactive view of the food delivery business across customer behaviour, restaurant performance, demand patterns, operational performance, and customer retention. The dashboard converts the analysis from the case study into an interactive business-facing format, allowing users to explore key patterns across different dimensions.

Dashboard Structure :

The dashboard consists of five pages, with selected pages using interactive buttons to switch between different analytical views.

Page	Focus
1. Business Overview	Overall business, customer, demand, and restaurant performance
2. Restaurant Performance	Restaurant-level demand, customer behaviour, and operations
3. Demand & Temporal Analysis	Demand, discounting, and cancellation patterns over time
4. Operational Performance	Rider wait time and kitchen preparation performance
5. Customer & Retention Analysis	Customer value, ordering behaviour, and retention

1.) Business Overview

What this page shows :

- The business received **21.32K orders** from approximately **12K unique customers** during September 2024 to January 2025.
- The total order value was **₹14.55M**, with a median order value of **₹597.45**.
- **Repeat customers generated ₹9.2M**, compared with **₹5.4M from one-time customers**, showing the importance of repeat customers.
- **Evening/Dinner** had the highest order volume at **12.5K orders**, followed by Lunch/Afternoon and Late Night.
- Revenue is highly concentrated among restaurants, with **Aura Pizzas generating ₹10.75M** and Swaad generating ₹3.55M.

Business takeaway :

The business is heavily driven by **repeat customers, evening/dinner demand, and a small number of restaurants**. This suggests that customer retention, peak-period capacity, and strong relationships with high-contributing restaurants are important areas for the business to focus on.

2.) Restaurant Performance

What this page shows :

- Restaurant-level **order volume** and **median operational performance**, including rider wait time and KPT.
- **Repeat customer rate** for each restaurant, helping compare customer retention across restaurant partners.
- The distribution of each restaurant's orders across **Evening/Dinner, Lunch/Afternoon, and Late Night**.
- A **restaurant slicer** allows the user to select a specific restaurant and explore its performance.

Business takeaway :

Restaurant performance varies across customer behaviour and operational metrics. The page helps the business identify restaurants with higher repeat customer rates, higher operational waiting times, and different demand

patterns, allowing restaurant-level issues and opportunities to be investigated rather than treating all restaurant partners the same.

3.) Demand & Temporal Analysis

What this page shows :

This page uses three views to understand how **customer demand, discounting, and cancellations change across time.**

- **Demand** : Shows order volume by time of day, day of week, and month. Evening/Dinner has the highest demand, while Saturday has the highest number of orders among the days shown.
- **Discount** : Shows the median discount offered across different times of day and days of the week. This helps compare how discounting varies across different demand periods.
- **Cancellations** : Shows customer and platform cancellation rates by month, allowing the business to track how cancellation patterns change over time.

Business takeaway :

Demand is concentrated around **Evening/Dinner**, while order volumes remain relatively similar across the five months. The discount view helps the business understand where higher discounts are being offered, while the cancellation view can be used to monitor changes in customer and platform cancellations over time.

4.) Operational Performance

What this page shows :

This page focuses on two operational measures : **Rider Wait Time** and **KPT (Kitchen Preparation Time)**.

- **Rider Wait Time:** Shows the median time riders wait at restaurants across different times of day and days of the week.
- It also compares rider wait time based on whether the **order-ready status was marked correctly, missed, or incorrectly**.
- **KPT:** Shows the median kitchen preparation time across different times of day and days of the week.
- The two views help separate **restaurant preparation time** from the time riders spend waiting for orders to be ready.

Business takeaway

Rider waiting time is highest during **Lunch/Afternoon (4.3 minutes)**, while the largest difference appears across order-ready marking status: orders marked **incorrectly have a median rider wait time of 7.2 minutes**, compared with **2.5**

minutes when marked correctly. KPT is also highest during Lunch / Afternoon at **16.8 minutes**.

These patterns point to **order-ready marking accuracy** and **restaurant preparation timing** as areas worth monitoring to improve operational efficiency and reduce rider waiting.

5.) Customer Value & Retention Analysis

What this page shows :

This page looks at **customer ordering behaviour, customer value and retention over time**.

- **Customer Value** : Shows the total revenue generated at each stage of the customer journey, from the 1st order through 11+ orders.
- It also compares the **median order value** for customers at different order stages.
- The customer distribution shows how many customers reached each order group, helping identify how quickly the customer base drops as order frequency increases.
- **Retention** : Shows how average customer retention changes week by week after a customer's first order.
- The cohort retention matrix compares retention patterns across different customer cohorts and weeks since their first order.

Business takeaway :

Revenue is heavily concentrated in customers' **first few orders**, while the number of customers reaching higher-order stages declines substantially. Median order value also decreases from **₹608 for the first three order groups to ₹504 for customers at the 11+ order stage**.

Retention drops sharply after the first week, falling from **8.90% in Week 1 to 4.66% by Week 10**. The cohort view allows the business to compare whether retention behaviour is consistent across different customer cohorts.

This page therefore helps the business understand **how customer value develops with repeat ordering and where customer retention drops over time**.

Overall Dashboard Purpose :

The Power BI dashboard converts the analysis from the food delivery business case study into an interactive format. It allows business users to quickly explore overall business performance, restaurant performance, demand and temporal patterns, operational performance, and customer value and retention.

The dashboard is intended to support business monitoring and exploration, while the detailed statistical analysis, driver analysis, recommendations, and limitations are documented separately in the main case study.
